### ABSTRACT

A field experiment was conducted during early *kharif* of 2008 on sandy clay loam soils of dryland farm of Sri Venkateswara Agricultural College, Tirupati to study the effect of nitrogen and zinc on yield and quality of guar (*Cyamopsis tetragonoloba* (L.) Taub.). "The experiment was laid out in a split-plot design and replicated thrice. The treatments consisted of three main plots viz., 20 Kg N ha<sup>-1</sup> (N<sub>1</sub>), 30 Kg N ha<sup>-1</sup> (N<sub>2</sub>) and 40 Kg N ha<sup>-1</sup> (N<sub>3</sub>) and four sub plot treatments viz; 0.5 % ZnSO<sub>4</sub> spray at 25 DAS (Z<sub>1</sub>), 0.5 % ZnSO<sub>4</sub> spray at 45 DAS (Z<sub>2</sub>), 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) and basal application of 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup> (Z<sub>4</sub>). At all the crop growth stages, nitrogen levels significantly influenced the dry matter production. The highest dry matter production was registered with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>), while it was the lowest with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). Yield attributes viz., number of clusters plant<sup>-1</sup>, number of pods cluster<sup>-1</sup>, number of pods plant<sup>-1</sup>, pod length, number of seeds pod<sup>-1</sup> and thousand seed weight were highest with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>), while they were at their lowest with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>) except clusters plant<sup>-1</sup> and pod length, which were lowest with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). The seed yield and stalk yield were highest with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) and they were at their lowest with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). Among the zinc management practices Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) resulted in highest seed and stalk yield. Application of 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup> (Z<sub>4</sub>) recorded the lowest yield. With regard to quality parameters, protein content was found to be the highest with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>), which was however, comparable with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) and it was lowest with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). The highest protein content was recorded with Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS), while it was lowest with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>). The combination of nitrogen levels and zinc management practices could not influence the protein content. The highest post harvest status of soil available phosphorus and potassium was recorded with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>).

**Key Words:** Dry Matter, Yield, Quality, Nitrogen, Zinc, Clusterbean

### INTRODUCTION

Clusterbean is grown for different purposes from very ancient time viz., vegetables, green fodder, and green manure and for production of seeds. Clusterbean seed is used as a concentrate for animals and for extraction of gum. Seeds of clusterbean containing 28-33% gum. The gum has its use in almost all types of industries viz., textiles, paper, petroleum, pharmaceuticals, food processing, cosmetics, mining explosives, oil drilling etc. India is earning crores in foreign exchange every year by exporting guar gum and recorded Rs. 731 crore was obtained in year 1998-99 (Anonymous, 2000). Therefore, India occupies top position in world trade of guar gum. The by product from gum extraction process is of a high value protein feed for cattle as it contains about 40% protein. Improving soil fertility is one of the most common tactics to increase agricultural production. Maintaining high levels of available Nitrogen and zinc, the two most limiting nutrients in soils, is a major challenges to ecologists and land managers. Nitrogen is essential for normal growth and development of clusterbean. Besides all these, it provides nutritive concentrate and adds to the fertility of soil by fixing considerable amount of atmospheric nitrogen (Naagar *et al.*, 2004). Earlier reports showed that combine application of nitrogen and zinc caused significant results in respect of grain yield and quality of crop. Therefore keeping this in view, present

## Research Article

study on effect of nitrogen and zinc on drymatter production, yield and quality of clusterbean crop was undertaken.

### MATERIALS AND METHODS

A field experiment conducted during early Kharif, 2008 at S.V. Agricultural College, Tirupati. The soil of the experimental site was sandy loam with pH 7.1, organic carbon 0.25%, available N 240 kg ha<sup>-1</sup>, available P<sub>2</sub>O<sub>5</sub> 25 kg ha<sup>-1</sup>, and K<sub>2</sub>O 229.7kg ha<sup>-1</sup> and zinc 0.7 mg kg<sup>-1</sup>. The experiment was laid out in split plot design with twelve treatment replicated thrice. The fertilizers were applied as per treatments. Entire quantity of N, P<sub>2</sub>O<sub>5</sub> and K<sub>2</sub>O was applied as a basal dose. Nitrogen was applied as per the main plot treatments i.e. N<sub>1</sub> @ 20 kg ha<sup>-1</sup>, N<sub>2</sub> @ 30 kg ha<sup>-1</sup> and N<sub>3</sub> @ 40 kg ha<sup>-1</sup>. The zinc was applied as per the sub plot treatments i.e. Z<sub>1</sub> -@ 0.5% ZnSO<sub>4</sub> spray at 25 DAS, Z<sub>2</sub> @ 0.5% ZnSO<sub>4</sub> spray at 45 DAS, Z<sub>3</sub> @ 0.5% ZnSO<sub>4</sub> spray at 25 and 45 DAS, Z<sub>4</sub> @ 20 kg ZnSO<sub>4</sub> ha<sup>-1</sup>.

The source of N, P, K and Zn are urea, single super phosphate, muriate of potash and zinc sulphate, respectively. The fertilizers were placed in the furrows made with hand hoe 5 cm away from seed rows and at a depth of 5 cm below the seed zone. The variety used in the experiment was "RGM 112". It is recommended for arid and semi-arid tract of the country and resistant to white fly. Agronomic Cultivation practices like field preparation, seeds and sowing, weeding, fertilizer application, and other plant protection measures were done for healthy crop growth and yield data observed in specific growth stages particularly 25, 50 and 75 DAS.

For dry matter production, five plants were selected at random from border rows leaving the extreme row in each plot and the plants were cut, air dried and then oven dried at 60°C, till constant weight was obtained and their weights were recorded. Dry matter production was recorded at 25, 50, 75 DAS and at harvest and expressed as kg ha<sup>-1</sup>. Similarly number of cluster per plant, number of pods per cluster, number of pods per plant, pod length, number of seeds per pod, thousand seed weight, seed yield and stalk yield are observed in appropriate plant growth stage.

Similarly in quality parameters crude protein content (%) and crude gum content (%) are analyzed by Microkjeldhal method (Juliano *et al.*, 1973) and Das method (Das *et al.*, 1977) respectively.

### RESULTS AND DISCUSSION

**i) Dry Matter Production:** Dry matter production of guar increased progressively with advance in age of the crop up to maturity.

#### **a) Dry Matter Production at 25 DAS**

Nitrogen levels and zinc management practices significantly influenced the dry matter production but their interaction could not show any significant effect (Table -1).

The highest dry matter production was noticed with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>) which was significantly superior to rest of the nitrogen levels. The next best treatment was N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) which was distinctly superior to N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). The highest dry matter production was recorded with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) and it was superior over the remaining three treatments which were found to be inferior and at par with each other. Significant interaction was not traceable between nitrogen levels and zinc management practices with regard to dry matter production.

#### **b) Dry Matter Production at 50 DAS**

Among the nitrogen levels, N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) has resulted in maximum dry matter production which was distinctly superior to the remaining two treatments, N<sub>3</sub> (40 Kg N ha<sup>-1</sup>) and N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). The lowest dry matter was recorded with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>) (Table - 2).

Zinc management practices significantly influenced the dry matter production at 50 DAS. The highest dry matter production was obtained with Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) which was distinctly superior to the remaining treatments. The next best treatment was Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS) followed by Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS). The lowest dry matter production was resulted with Z<sub>4</sub>

(20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>). The interactions effect was significant at 50 DAS. Irrespective of nitrogen levels, Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) resulted in highest dry matter production while at all zinc management practices, application of 30 Kg N ha<sup>-1</sup> (N<sub>2</sub>) resulted in highest dry matter production. The highest dry matter production was obtained with N<sub>2</sub>Z<sub>3</sub> (30 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) while N<sub>1</sub>Z<sub>4</sub> (20 Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) accounted for the lowest dry matter production.

**Table 2: Dry matter production (kg ha<sup>-1</sup>) of guar at 50 DAS as influenced by nitrogen and zinc nutrition**

| Treatments     | Z <sub>1</sub> | Z <sub>2</sub> | Z <sub>3</sub> | Z <sub>4</sub> | Mean |

| Z at N      | 68    | 203       |

### c) Dry Matter Production at 75 DAS

Significant disparity in dry matter production at 75 DAS was noticed due to nitrogen levels and zinc management practices (Table -1).

The highest dry matter production was with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>) followed by N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) while the lowest dry matter production was obtained with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). Significantly highest dry matter production was recorded with Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) which was significantly superior to the remaining treatments and Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS) was the next best treatment. The lowest dry matter production was recorded with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>).

## Research Article

The interaction effect of nitrogen levels and zinc management practices failed to exert any significant influence on dry matter production at 75 DAS

### d) Dry Matter Production at Harvest

The highest dry matter production was obtained with N<sub>3</sub> (40Kg N ha<sup>-1</sup>) followed N<sub>2</sub> (30 Kg N ha<sup>-1</sup>). Application of 20 Kg N ha<sup>-1</sup>(N<sub>1</sub>) was found to record the lowest dry matter production (Table -1).

The highest dry matter production was recorded with Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) which was significantly superior to the remaining treatments. The next best treatment was found to be Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS). The lowest dry matter production was observed with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) which was comparable with Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS).

Interaction effect of nitrogen levels and zinc management practices was found to be non significant. Enhanced dry matter production with adequate supply of nitrogen, as evidenced in this investigation corroborates the findings of Mohmoud *et al.*, (1996); Sanjeev Kumar *et al.*, (2007) and Uday Burman *et al.*, (2007).

### ii) Yield Attributes and Yield

a) **Number of Clusters Plant<sup>-1</sup>**: Nitrogen levels, zinc management practices as well as their interaction effect exerted significant influence on the number of clusters plant<sup>-1</sup> in guar (Table - 3).

**Table 3: Yield attributes of guar as influenced by nitrogen and zinc nutrition**

The highest number of clusters plant<sup>-1</sup> was recorded with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>), which was on par with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>). The lowest number of clusters plant<sup>-1</sup> was observed in N<sub>1</sub> (20 Kg N ha<sup>-1</sup>) which was in parity with N<sub>3</sub> (40KgNha<sup>-1</sup>). Application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) resulted in the highest number of clusters plant<sup>-1</sup>. The lowest number of clusters plant<sup>-1</sup> was recorded with Z<sub>4</sub> (20 Kg

### Research Article

ZnSO<sub>4</sub> ha<sup>-1</sup>) and Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS) which were on par with Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS).

**b) Number of Pods Cluster<sup>-1</sup>:** Number of pods cluster<sup>-1</sup> was significantly influenced due to nitrogen levels, zinc management practices and also their interaction (Table - 3).

The highest number of pods cluster<sup>-1</sup> was recorded with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) which was significantly superior to rest of the nitrogen levels. The next best treatment was N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). Application of 40 Kg N ha<sup>-1</sup> (N<sub>3</sub>) was found to be the lowest. The highest number of pods cluster<sup>-1</sup> was noticed with Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) which was significantly superior to other levels. The next best treatment was Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS) followed by Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS). The lowest number of pods cluster<sup>-1</sup> was observed in Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>).

The interaction effect of nitrogen levels and zinc management practices was conspicuous. Irrespective of the Zinc management practices, application of 30 Kg N ha<sup>-1</sup> (N<sub>2</sub>) produced more number of pods cluster<sup>-1</sup>. At all the nitrogen levels, Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) recorded more number of pods cluster<sup>-1</sup>. The highest number of pods cluster<sup>-1</sup> was recorded with N<sub>2</sub>Z<sub>3</sub> (30Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS). Application 30KgN ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25DAS (N<sub>2</sub>Z<sub>1</sub>) was found to be the next best. The lowest number of pods cluster<sup>-1</sup> was found with N<sub>3</sub>Z<sub>4</sub> (40Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) and was on par with N<sub>1</sub>Z<sub>4</sub> (20 Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>).

**c) Number of Pods Plant<sup>-1</sup>:** Nitrogen levels and zinc management practices as well as their interaction have exerted significant influence on number of pods plant<sup>-1</sup> (Table - 3).

Application of 30 Kg N ha<sup>-1</sup> (N<sub>2</sub>) has resulted in highest number of pods plant<sup>-1</sup> which was significantly superior to rest of the nitrogen levels. Application of 40 Kg N ha<sup>-1</sup> (N<sub>3</sub>) was found to be inferior but was comparable with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). Application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) significantly increased the number of pods plant<sup>-1</sup> compared to other zinc management practices. The next best treatment was Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS) followed by Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS). The lowest number of pods plant<sup>-1</sup> was noticed with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>).

With regard to interaction, application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) recorded higher number of pods plant<sup>-1</sup> at all the nitrogen levels tried. Irrespective of zinc management practices, N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) was found to be superior. The highest number of pods plant<sup>-1</sup> was recorded with N<sub>2</sub>Z<sub>3</sub> (30 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS). The next best treatment was N<sub>3</sub>Z<sub>3</sub> (40 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) which was however on par with N<sub>1</sub>Z<sub>3</sub> (20 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) and N<sub>2</sub>Z<sub>1</sub> (30 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 DAS). Application of 40Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup> (N<sub>3</sub>Z<sub>4</sub>) was found to be the least performing treatment.

**d) Pod Length:** Pod length was significantly influenced by nitrogen levels and zinc management practices but their interaction could not have any significant effect (Table - 4).

Maximum pod length was recorded in both N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) and N<sub>3</sub> (40 Kg N ha<sup>-1</sup>) treatments. The shortest pods were observed with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>).

Application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) resulted in maximum pod length, while Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) was found to record the lowest pod length which was comparable with Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS) and Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS).

The Interaction effect of nitrogen and zinc management practices was found to be non significant.

**e) Number of Seeds Pod<sup>-1</sup>:** Except Interaction, nitrogen levels and zinc management practices could significantly influence the number of seeds pod<sup>-1</sup> (Table - 4).

Application of 30 Kg N ha<sup>-1</sup> (N<sub>2</sub>) resulted in the highest number of seeds pod<sup>-1</sup> which was on par with 20 Kg N ha<sup>-1</sup> (N<sub>1</sub>). The lowest number of seeds pod<sup>-1</sup> was recorded in N<sub>3</sub> (40 Kg N ha<sup>-1</sup>). Among the zinc management practices, application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) was found to record the highest number of seeds pod<sup>-1</sup>. The next best treatment was Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS) which was however on par with Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS). The lowest number of seeds pod<sup>-1</sup> was produced

# Research Article

in Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>). Regarding the interaction effect there was no significant influence on number of seeds pod<sup>-1</sup>.

**f) Thousand Seed Weight:** Thousand seed weight was found to be significantly influenced only by zinc management practices. Nitrogen levels and interaction could not have any effect on the thousand seed weight (Table - 4).

**Table 4: Yield attributes of guar as influenced by nitrogen and zinc nutrition**

| Treatments                       | Pod length (cm) | Seeds/pod | Thousand Seed Weight (g) |
|----------------------------------|-----------------|-----------|--------------------------|
| <b>Nitrogen levels</b>           |                 |           |                          |

**Figure 1: Seed yield and Stalk yield (kg ha<sup>-1</sup>) of guar as influenced by nitrogen and zinc nutrition**

## Research Article

Significantly the highest test weight was obtained with Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) followed by Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS). The lowest test weight was recorded with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) which was found significantly inferior to rest of the treatments.

Yield attributes viz., number of clusters plant<sup>-1</sup>, number of pods cluster<sup>-1</sup>, number of pods plant<sup>-1</sup>, pod length, number of seeds pod<sup>-1</sup> and thousand seed weight were highest with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>), while they were at their lowest with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>) except clusters plant<sup>-1</sup> and pod length, which were lowest with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>) (Figure 5.4-5.9). Higher dry matter production and the efficient translocation of accumulated assimilates to the reproductive parts under comfortable nitrogen nutrition might be responsible for the beneficial effect on elevating the stature of all the yield attributes. Similar results have been reported by Singh and Singh (1989) and Sharma and Nehara (2004).

**g) Seed Yield:** Seed yield was significantly influenced by nitrogen levels, zinc management practices and their interaction (Table 5. and Figure1).

**Table 5: Seed and Stalk yield (kg ha<sup>-1</sup>) of guar as influenced by nitrogen and zinc nutrition**

| Treatment | Z1   |       | Z2   |       | Z3   |       | Z4   |       | Mean |       |
|-----------|------|-------|------|-------|------|-------|------|-------|------|-------|
|           | Seed | Stalk | Seed | Stalk | Seed | Stalk | Seed | Stalk | Seed | Stalk |
| N1        | 613  | 832   | 559  | 745   | 808  | 1082  | 513  | 639   | 623  | 825   |
| N2        | 830  | 971   | 727  | 859   | 1053 | 1579  | 666  | 770   | 819  | 1045  |
| N3        | 715  | 945   | 685  | 859   | 813  | 1197  | 554  | 646   | 692  | 912   |
| Mean      | 719  | 916   | 657  | 822   | 891  | 1286  | 577  | 685   | --   | --    |

| Interaction | SEm±  |       | CD (0.05) |       |
|-------------|-------|-------|-----------|-------|
|             | Seed  | Stalk | Seed      | Stalk |
| N           | 10.76 | 16.72 | 42        | 66    |
| Z           | 14.36 | 13.77 | 43        | 41    |
| N at N      | 24.08 | 26.58 | 76        | 89    |
| Z at N      | 24.87 | 23.86 | 74        | 71    |

The highest seed yield was obtained with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) which was superior to all other treatments. The next best treatment was 40 Kg N ha<sup>-1</sup> (N<sub>3</sub>) which was significantly higher compared to 20 Kg N ha<sup>-1</sup> (N<sub>1</sub>). The lowest yield was obtained in N<sub>1</sub> (20 Kg N ha<sup>-1</sup>). The increase in seed yield with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) was 31.5 and 18.3 per cent higher than with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>) and N<sub>1</sub> (20 Kg N ha<sup>-1</sup>), respectively. Clear disparity in seed yield was noticed between any two of four zinc treatments tried. The highest seed yield was obtained with application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) which was significantly superior to all other zinc treatments tried. Application of 0.5 % ZnSO<sub>4</sub> spray at 25 DAS (Z<sub>1</sub>) was the next best treatment followed by Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS). Application of 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup> (Z<sub>4</sub>) resulted in the lowest seed yield. Application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) increased seed yield by 54.4% over 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup> (Z<sub>4</sub>) while the yield increase was 35.6% and 23.9% over Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS) and Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS), respectively.

Seed yield varied significantly due to the interaction effect of nitrogen levels and zinc management practices. At all the nitrogen levels tried, Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) resulted in the highest seed yield. Irrespective of zinc management practices, N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) resulted in highest seed yield. The highest seed yield was obtained with N<sub>2</sub>Z<sub>3</sub> (30 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS). The lowest seed yield was recorded with N<sub>1</sub>Z<sub>4</sub> (20 Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>). Application of 30 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (N<sub>2</sub>Z<sub>3</sub>) increased the seed yield by 105.3% over 20 Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup> (N<sub>1</sub>Z<sub>4</sub>).

## Research Article

Higher guar yield with application of nitrogen, as noticed in the present investigation confirms the documented evidence of Baboo and Rana (1995), Patel *et al.*, (2005), Sharma and Nehara (2004) and Rathore *et al.*, (2007).

**h) Stalk Yield:** Stalk yield was significantly influenced by nitrogen levels, zinc management practices and also their interaction (Table 5 and Figure 1).

The highest stalk yield was obtained with N<sub>2</sub> (20 Kg N ha<sup>-1</sup>) which was significantly superior to rest of the nitrogen levels. Application of 40 Kg N ha<sup>-1</sup> (N<sub>3</sub>) was the next best treatment. The stalk yield was the lowest with 20 Kg N ha<sup>-1</sup> (N<sub>1</sub>).

The stalk yield was the highest with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) which was significantly superior to all the other zinc management practices. Application of 0.5 % ZnSO<sub>4</sub> spray at 25 DAS (Z<sub>1</sub>) was found to be the next best treatment followed by 0.5 % ZnSO<sub>4</sub> spray at 25DAS (Z<sub>2</sub>). The lowest stalk yield was noticed with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup> (Z<sub>4</sub>).

Irrespective of the zinc management practices imposed, N<sub>2</sub> (30 Kg N ha<sup>-1</sup>) resulted in highest stalk yield, while at all the nitrogen levels tried, Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS) accounted for highest stalk yield. Among the interactions, significantly highest stalk yield was recorded with N<sub>2</sub>Z<sub>3</sub> (30 Kg N ha<sup>-1</sup> along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS). The lowest stalk yield was obtained with N<sub>1</sub>Z<sub>4</sub> (20 Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) which was comparable with N<sub>3</sub>Z<sub>4</sub> (40Kg N ha<sup>-1</sup> along with 20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>).

These findings are in conformity with Singh and Singh (1989), Baboo and Rana (1995), Yadav *et al.*, (2003) and Patel *et al.*, (2005).

### iii) QUALITY PARAMETERS

#### a) Crude Protein Content

Nitrogen levels and zinc management practices could have significant influence on the protein content but their interaction could not have any significant effect on protein content. (Table - 6).

**Table 6: Crude protein content (%), Crude gum content (%) and Gum yield (kg ha<sup>-1</sup>) of seed as influenced by nitrogen and zinc nutrition.**

| Treatments                       | Quality parameters |         |               |                 |
|----------------------------------|--------------------|---------|---------------|-----------------|
|                                  | Crude content      | protein | Crude content | gum Gum content |
| <b>Nitrogen levels</b>           |                    |         |               |                 |
| N <sub>1</sub>                   | 25.8               |         | 30.0          | 187             |

| Z <sub>4</sub>                   | 25.9               |         | 29.9          | 176             |
| SEm±                             | 0.22               |         | 0.20          | 9.2             |
| CD (P = 0.05)                    | 0.7                |         | NS            | 27              |
| N×S                              | NS                 |         | NS            | NS              |

The highest protein content was recorded with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>), which was on par with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>). The lowest protein content was recorded with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>) which was significantly lesser than the other nitrogen levels. Zinc management practices influenced the protein content of guar with distinct disparity between any two zinc treatments tried. Application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>)

## Research Article

recorded the highest protein content followed by Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS) and Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS) with significant disparity among them. The lowest protein content was recorded with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>) which was significantly lesser than rest of the treatments. Interaction was not traceable statistically. These results are in agreement with the findings of Singh and Singh (1989) and Baboo and Rana (1995).

### B) Crude Gum Content

Effect of nitrogen levels, zinc management practices and their interaction could not be statistically traceable (Table -6 and Figure 1).

### c) Gum Yield

Different treatments had a significant influence on the gum yield but their interaction fails to exert any significant influence on the gum yield (Table -6 and Figure 2).

Figure 2: Crude gum content of seed (%) of guar as influenced by nitrogen and zinc nutrition

Figure 3: Gum yield (kg ha<sup>-1</sup>) of guar as influenced by nitrogen and zinc nutrition

## Research Article

The highest gum yield was recorded with N<sub>2</sub> (30 Kg N ha<sup>-1</sup>), however it was comparable with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>). The lowest gum yield was obtained with N<sub>1</sub> (20 Kg N ha<sup>-1</sup>) which was in parity with N<sub>3</sub> (40 Kg N ha<sup>-1</sup>). Application of 0.5 % ZnSO<sub>4</sub> spray at 25 and 45 DAS (Z<sub>3</sub>) was found to produce highest gum yield followed by Z<sub>1</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 DAS) and Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>). The lowest gum yield was recorded with Z<sub>2</sub> (0.5 % ZnSO<sub>4</sub> spray at 45 DAS) which was comparable with Z<sub>4</sub> (20 Kg ZnSO<sub>4</sub> ha<sup>-1</sup>). Interaction was found to be non-significant.

Based on the present study it can be concluded that application of 30 Kg N ha<sup>-1</sup> (N<sub>2</sub>) was found to be effective and economic for higher yield and returns. The treatment Z<sub>3</sub> (0.5 % ZnSO<sub>4</sub> spray at 25 and 45DAS) registered the highest seed yield and better economic returns. Application of 30 Kg N ha<sup>-1</sup> (N<sub>2</sub>) along with 0.5 % ZnSO<sub>4</sub> spray at 25 and 45DAS (Z<sub>3</sub>) performed better than other interactions in terms of growth and yield of guar. The combination of nitrogen levels and zinc management practices could not influence the protein content. Neither nitrogen levels, zinc management practices nor could their interaction significantly influence the gum content.
